Examen Final 177508 175904

177508 - Uriel Miranda Miñón

175904 - Jorge III Altamirano Astorga

3.1 Bootstrap paramétrico.

• Escribe la función de verosimilitud y calcula el estimador de máxima verosimilitud para σ^2 . Supongamos que observamos los datos x (en la carpeta datos), ¿Cuál es tu estimación de la varianza?

Dada la verosimilitud:

$$\mathcal{L}(\sigma^{2}|x_{0}, x_{1}, ..., x_{n}) = \prod_{i=0}^{n} p(\sigma^{2}) = \prod_{k=0}^{n} \left[\frac{1}{\sqrt{2\pi\sigma^{2}}} exp\left(-\frac{1}{2\sigma^{2}} (x - x_{k})^{2} \right) \right]$$

Log Verosimilitud sería:

$$\updownarrow(\sigma^2) = \log \mathcal{L}(\sigma^2) = \sum \log p(\sigma^2)$$

$$= \log \left\{ \Pi \left[\frac{1}{\sqrt{2\pi\sigma^2}} exp \left(-\frac{1}{2\sigma^2} (x - x_k)^2 \right) \right] \right\} = \sum_{k=0}^n \log \left\{ \left[\frac{1}{\sqrt{2\pi\sigma^2}} exp \left(-\frac{1}{2\sigma^2} (x - x_k)^2 \right) \right] \right\}$$

por leyes de los logaritmos...

$$= \sum_{k=0}^{n} \left[log \left(\frac{1}{\sqrt{2\pi\sigma^2}} \right) - \left(\frac{1}{2\sigma^2} (x - x_k)^2 \right) \right] = -n \log \sqrt{2\pi\sigma^2} - \sum_{k=0}^{n} \left[\frac{1}{2\sigma^2} (x - x_k)^2 \right] = -n \log \sqrt{2\pi\sigma^2} - \frac{1}{2\sigma^2} \sum_{k=0}^{n} (x - x_k)^2$$

$$= -\frac{n}{2} \left(log \ 2\pi + log \ \sigma^2 \right) - \frac{1}{2\sigma^2} \sum_{k=0}^{n} (x - x_k)^2$$

Si lo derivamos...

$$\frac{\partial \updownarrow}{\partial \sigma^2} = -n \ \sigma^2 + \sum_{k=0}^{n} (x - x_k)^2 = 0$$

Despejando...

$$\sigma^2 = \frac{\sum_{k=0}^{n} (x - x_k)^2}{n} = \frac{\sum_{k=0}^{n} (-x_k)^2}{n}$$

Función de máxima verosimilitud

```
load("data_est_comp/x.RData")
load("data_est_comp/rabbits.RData")
sigma_mv <-function(n,x) sum(x^2)/n
n <- length(x)
paste0("n=",n)</pre>
```

[1] "n=150"

```
\sigma^2 = 131.291
```

```
varianza <- sigma_mv(n,x)
varianza</pre>
```

[1] 131.291

• Aproxima el error estándar de la estimación usando bootstrap paramétrico y realiza un histograma de las replicaciones bootstrap.

```
error = 0.6480146
```

```
sigma_hat <- varianza
mu <- 0

set.seed(175904)
thetaBoot <- function(){
    # Simular X_1*,...X_N* con distribución N(mu_hat, sigma_hat^2)
    x_boot <- rnorm(n, mean = 0, sd = sqrt(sigma_hat))
    # Calcular sigma*
    mu_boot <- mu
    (1 / n * sum((x_boot - mu_boot)^2))
}
sims_boot <- rerun(3000, thetaBoot()) %>% flatten_dbl()
ERR <- sqrt(1 / 2999 * sum((sims_boot - mean(sigma_hat))^2))
ERR</pre>
```

[1] 15.11619
hist(sims_boot)

Histogram of sims_boot

3.2 Análisis bayesiano

• Continuamos con el problema de hacer inferencia de σ^2 . Comienza especificando una inicial Gamma Inversa, justifica tu elección de los parámetros de la distribución inicial y grafica la función de densidad.

Justificamos que utilizamos los parámetros $\alpha=800, \beta=14$ debido a la gráfica del punto anterior. Dado que deseamos tener una función Gamma que aproxime dicha forma.

```
x_gamma <- rgamma(2000, shape = 800, rate = 14)
x_igamma <- (1 / x_gamma) %>% as.data.frame()
x_gamma %>% summary
##
      Min. 1st Qu.
                    Median
                               Mean 3rd Qu.
                                                Max.
     49.77
             55.82
                     57.18
                              57.22
                                      58.57
                                               63.53
x_igamma %>% summary
##
##
           :0.01574
    Min.
    1st Qu.:0.01707
    Median :0.01749
##
           :0.01750
    3rd Qu.:0.01792
##
    Max.

ggplot(x_igamma, aes(x = x_igamma)) +
 geom_histogram(aes(y = ..density..))
```

Don't know how to automatically pick scale for object of type data.frame. Defaulting to continuous.
`stat_bin()` using `bins = 30`. Pick better value with `binwidth`.

• Calcula analíticamente la distribución posterior.

$$p(\theta|x) \propto p(x|\theta)p(\theta) = \frac{1}{(\sigma^2)^{N/2}} exp\left(-\frac{1}{2\sigma^2} \sum_{i=1}^{N} (x_i - \mu)^2\right) exp\left(-\frac{1}{2\tau^2} (\mu - m)^2\right) \frac{1}{(\sigma^2)^{\alpha+1}} exp\left(-\frac{\beta}{\sigma^2}\right)$$

i.e.

$$\sigma^2 | \mu, x \sim GI\left(\frac{N}{2} + \alpha, \sum_{i=1}^n \frac{(x_i - \mu)^2}{2} + \beta\right)$$

$$(11.45823|0,x) \sim GI\left(\frac{150}{2} + 800, \sum_{i=1}^{n} \frac{(x_i - 0)^2}{2} + 14\right)$$

 Realiza un histograma de simulaciones de la distribución posterior y calcula el error estándar de la distribución.

 $error_{std} = 14.86156$

```
xb_gamma <- rgamma(2000, shape = (n/2)+3, rate = sum(x^2)/2+3)
xb_igamma <- (1 / xb_gamma) %>% as.data.frame()
```

```
ggplot(xb_igamma, aes(x = xb_igamma)) +
geom_histogram(aes(y = ..density..)) +
geom_vline(xintercept = mean(xb_igamma$., na.rm = T))
```

Don't know how to automatically pick scale for object of type data.frame. Defaulting to continuous.
`stat_bin()` using `bins = 30`. Pick better value with `binwidth`.

```
ERR_2 <- sqrt(1 / 2000 * sum((xb_igamma - sigma_hat) ^ 2))
ERR_2</pre>
```

[1] 14.86156

4. Metrópolis

En la tarea de Análisis Bayesiano (respuestas aquí programaste un algoritmo de Metropolis para el caso Normal con varianza conocida. En el ejercicio de la tarea los saltos se proponían de acuerdo a una distribución normal: N(0, 5). Para este ejercicio modifica el código con el fin de calcular el porcentaje de valores rechazados y considera las siguientes distribuciones propuesta: a) N(0,0.2), b) N(0,5) y c) N(0,20).

• 4.1 Genera valores de la distribución posterior usando cada una de las distribuciones propuesta, utiliza la misma distribución inicial y datos observados que utilizaste en la tarea (realiza 6000 pasos). Grafica los primeros 2000 pasos de la cadena. Comenta acerca de las similitudes/diferencias entre las gráficas.

Claramente entre el segundo parámetro de N sea más grande, en el código sd_prop hay más distancia (varianza) entre los pasos. Por lo que se ven mucho más espaciados entre paso y paso. 0.2 se ve casí como una "mancha", mientra 5 y 20 se ven distanciados.

```
prior <- function(mu = 100, tau = 10){

• 4.2 Calcula el porcentaje de valores rechazados, compara los resultados y explica a que se deben las diferencias.

```
A las mencionadas "varianzas" entre pasos. \sigma | rechazo — | — 0.2 | 5.56% 5 | 57.30% 20 | 86.91% rechazo <- data.frame(sd = c(0.2,5,20), rechazo_paso =c(rp0.2,rp5,rp20)) rechazo  
## sd rechazo_paso
```

```
## sd rechazo_paso
## 1 0.2 0.05566667
## 2 5.0 0.57300000
## 3 20.0 0.86916667
```

• 4.3 Elimina las primeras 1000 simulaciones y genera histogramas de la distribución posterior para cada caso, ¿que distribución propuesta nos da la representación más cercana a la verdadera distribución posterior? (compara las simulaciones de los tres escenarios de distribución propuesta con la distribución posterior calculada de manera analítica)

Es mucho más aproximado N(0,5)

```

5. Modelos jerárquicos

• 5.1 Si piensas en este problema como un lanzamiento de monedas, ¿a qué corresponden las monedas y los lanzamientos?

Las monedas corresponden a los conejos y los lanzamientos a los experimentos. Donde θ_1 en el caso de los lanzamientos corresponde a la probabilidad de sacar águila o sol; en el caso de los conejos, es la probabilidad de desarrollar o no un tumor.

• 5.2 La base de datos rabbits contiene las observaciones de los 71 experimentos, cada renglón corresponde a una observación.

rabbits

• Realiza un histograma de la distribución posterior de μ , κ . Comenta tus resultados.

```
k_pasos <- jags_fit_conejos$BUGSoutput$sims.matrix[,2]
k_pasos <- data.frame(k = k_pasos)
mu_pasos <- jags_fit_conejos$BUGSoutput$sims.matrix[,3]
mu_pasos <- data.frame(mu = mu_pasos)
g1 <- ggplot(k_pasos, aes(x = k)) +
    geom_histogram(aes(y = ..density..)) +
    ggtitle("Posterior de K")
g2 <- ggplot(mu_pasos, aes(x = mu)) +
    geom_histogram(aes(y = ..density..)) +
    ggtitle("Posterior de Mu")
grid.arrange(g1,g2,ncol=2)</pre>
```

```
## `stat_bin()` using `bins = 30`. Pick better value with `binwidth`.
## `stat_bin()` using `bins = 30`. Pick better value with `binwidth`.
```

• 5.3 Realiza una gráfica de boxplots con las simulaciones de cada parámetro θ_j , la gráfica será similar a la realizda en la clase de modelos probabilísticos (clase 9). Comenta tus resultados

```
p <- jags_fit_conejos$BUGSoutput$sims.matrix[,-c(1:3)] %>% data.frame
med_p_52 <- colMeans(p)
q <- gather(p,key = p)
ggplot(q, aes(p, value)) + geom_boxplot()</pre>
```

• 5.4 Ajusta un nuevo modelo utilizando una iniciales Beta(10,10) y Gamma(0.51,0.01)G para μ y κ (lo demás quedará igual). Realiza una gráfica con las medias posteriores de los parámetros θ_j bajo los dos escenarios de distribuciones iniciales. En el eje horizontal grafica las medias posteriores del modelo ajustado en 6.2 y en el eje vertical las medias posteriores del modelo modelo en 6.4. ¿Cómo se comparan?

No importan la "a priori", pues debido a los 1000 puntos de prueba de calentamiento se comporta aproximando a la posterior. Por lo que no hay mucha diferencia.

```
modelo_conejos54.txt <-
'
model{
    for(i in 1 : N) {
        y[i] ~ dbern(p[expr[i]])
    }
    for(j in 1 : nExp) {
        p[j] ~ dbeta(a, b)
    }
    a <- mu*k
    b <- (1-mu)*k
    mu ~ dbeta(10, 10)
    k ~ dgamma(.51, 0.01)
}
'
cat(modelo_conejos54.txt, file = 'modelo_conejos54.txt')
jags_fit_conejos54 <- jags(
    model.file = "modelo_conejos54.txt",  # modelo de JAGS</pre>
```

```
